

# New Direction for TPC

by

**Michael Stonebraker**

# Outline

- ◆ 1985
- ◆ 1985-88
- ◆ PAFS
- ◆ TPC-H
- ◆ The future

# 1985

- ◆ **Jim Gray writes debit-credit benchmark**
  - ◆ **And gets his friends to be co-authors**
  - ◆ **Commercial systems do about 25 TPS**
    - ◆ **Obviously inadequate**
  
- ◆ **Jim Gray starts HPTS**
  - ◆ **Goal is 1000 TPS (x40)**

# 1985-88

- ◆ Lots of ideas generated on improving OLTP performance
  - ◆ Facilitated by HPTS
- ◆ Lots of apples-to-oranges debit-credit benchmarks
  - ◆ With conventional vendor marketing spin
- ◆ But performance improves by an order of magnitude

# Obvious Need for

- ◆ **A level playing field for debit-credit**
- ◆ **A non-vendor organization to carry debit-credit forward**
  
- ◆ **Enter TPC and TPC-A**

# Characteristics of Debit-Credit

- ◆ **Pressing need**
  - ◆ **for better OLTP performance**
- ◆ **Application focused**
  - ◆ **Cash a check**
- ◆ **Simple**
  - ◆ **5 commands, 5 pages of specification**
- ◆ **Result was vendor focus and much better OLTP systems**

# Meta - Characteristics

- ◆ Find a **P**ressing need
- ◆ Find a simple **A**pplication
- ◆ **F**ocus the vendor community
- ◆ To provide better **S**ystems

**PAFS!**

# TPC-H (PAFS)

- ◆ Application/schema doesn't correspond to an obvious business problem
  - ◆ schema seems unnatural
  - ◆ see Pat's O'Neil's talk

# TPC-H (PAFS)

- ◆ Way too many queries (22)
- ◆ And queries seem politically gerrymandered
  - ◆ Can't use materialized views

# TPC-H (PAFS)

- ◆ No load component in TPC-H
- ◆ Users want the ability to perform incremental/trickle load

# TPC-H (PAFS)

- ◆ **Out-of-box experience awful for most systems**
- ◆ **Data base design way too hard – too many knobs**
- ◆ **And automatic tools don't work very well**
- ◆ **RDBMS considered too hard to use by many**

# TPC-H (PAFS)

- ◆ Scalability over a range of sizes is a big issue
- ◆ Ability to add resources on the fly is a big issue

# TPC-H (PAFS)

- ◆ Nobody recovers from the data base log
- ◆ No replication in TPC-H

# TPC-H (PAFS)

- ◆ Major warehouse vendors (e.g. Teradata, Netezza) ignore TPC-H
- ◆ Analysts (Forrester, Gartner) say TPC-H is irrelevant

# TPC-H (PAFS)

- ◆ **Current leaders run on silly hardware configurations**
  - ◆ **E.g. 1 Terabyte of disk for a 30 Gbyte configuration (32 X)**

# TPC-H

- ◆ A failure by PAFS standards
- ◆ At the very best is “long in the tooth”
  - ◆ Follow-on effort (TPC-DS) is worse by PAFS standards
- ◆ And TPC progress is at the speed of molasses

# TPC-H

- ◆ A failure by PAFS standards
- ◆ At the very best is “long in the tooth”
  - ◆ Follow-on effort (TPC-DS) is worse by PAFS standards
- ◆ And TPC progress is at the speed of **very slow molasses**
  - ◆ E.g. little stomach to fix these issues

# TPC-C

- ◆ **Essentially same comments apply**

# Summary of TPC

- ◆ **Is very slow moving**
- ◆ **Seems vendor dominated**
  - ◆ **Political and not user focused**
- ◆ **Not focused on PAFS**

# So What to Do?

- ◆ **Go back to your roots**
- ◆ **E.g. PAFS**
  - ◆ **In your traditional market**
  - ◆ **In new markets**

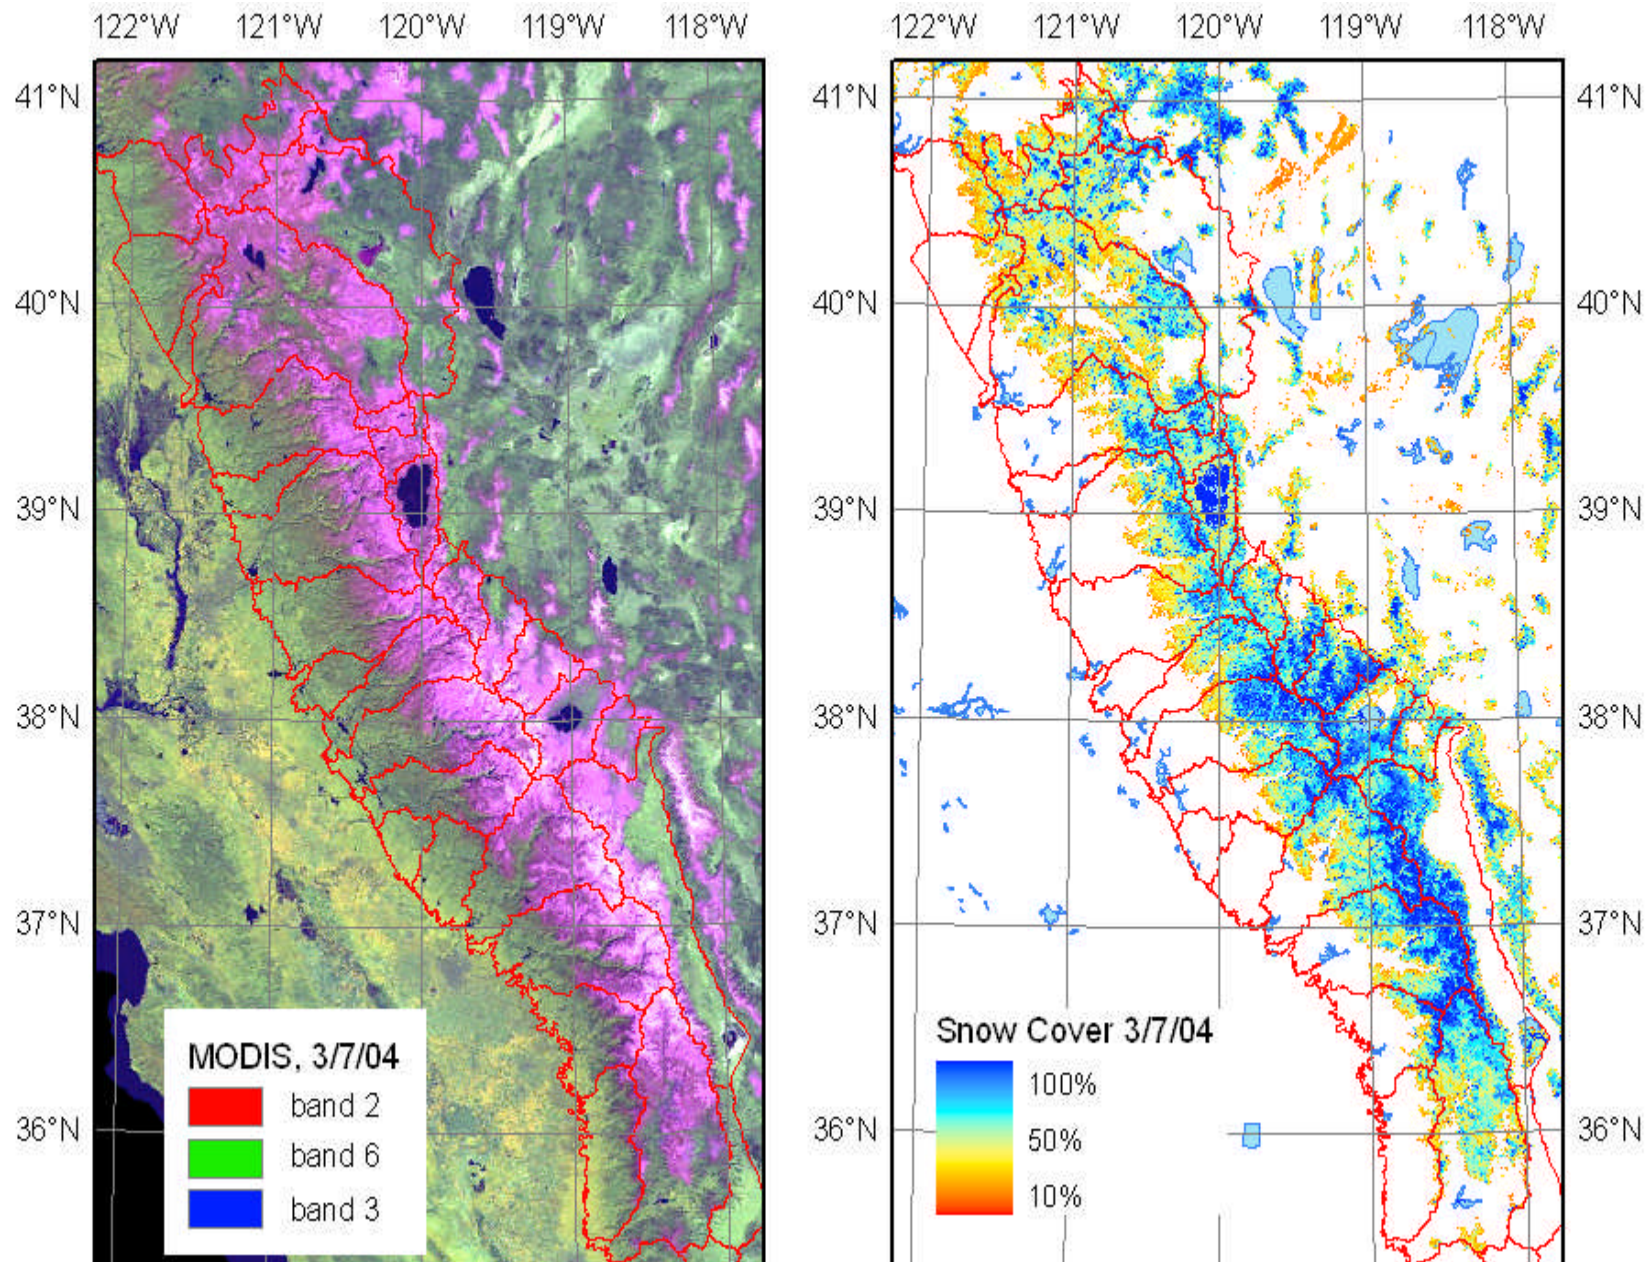

# Example – One Among Many

- ◆ **Science applications (e.g. Chemistry, Earth Sciences, Remote Sensing, ....)**
- ◆ **Universally hate current RDBMS**

Nearest neighbor queries, time series queries

# Snow Cover in the Sierras

# Protein Structure

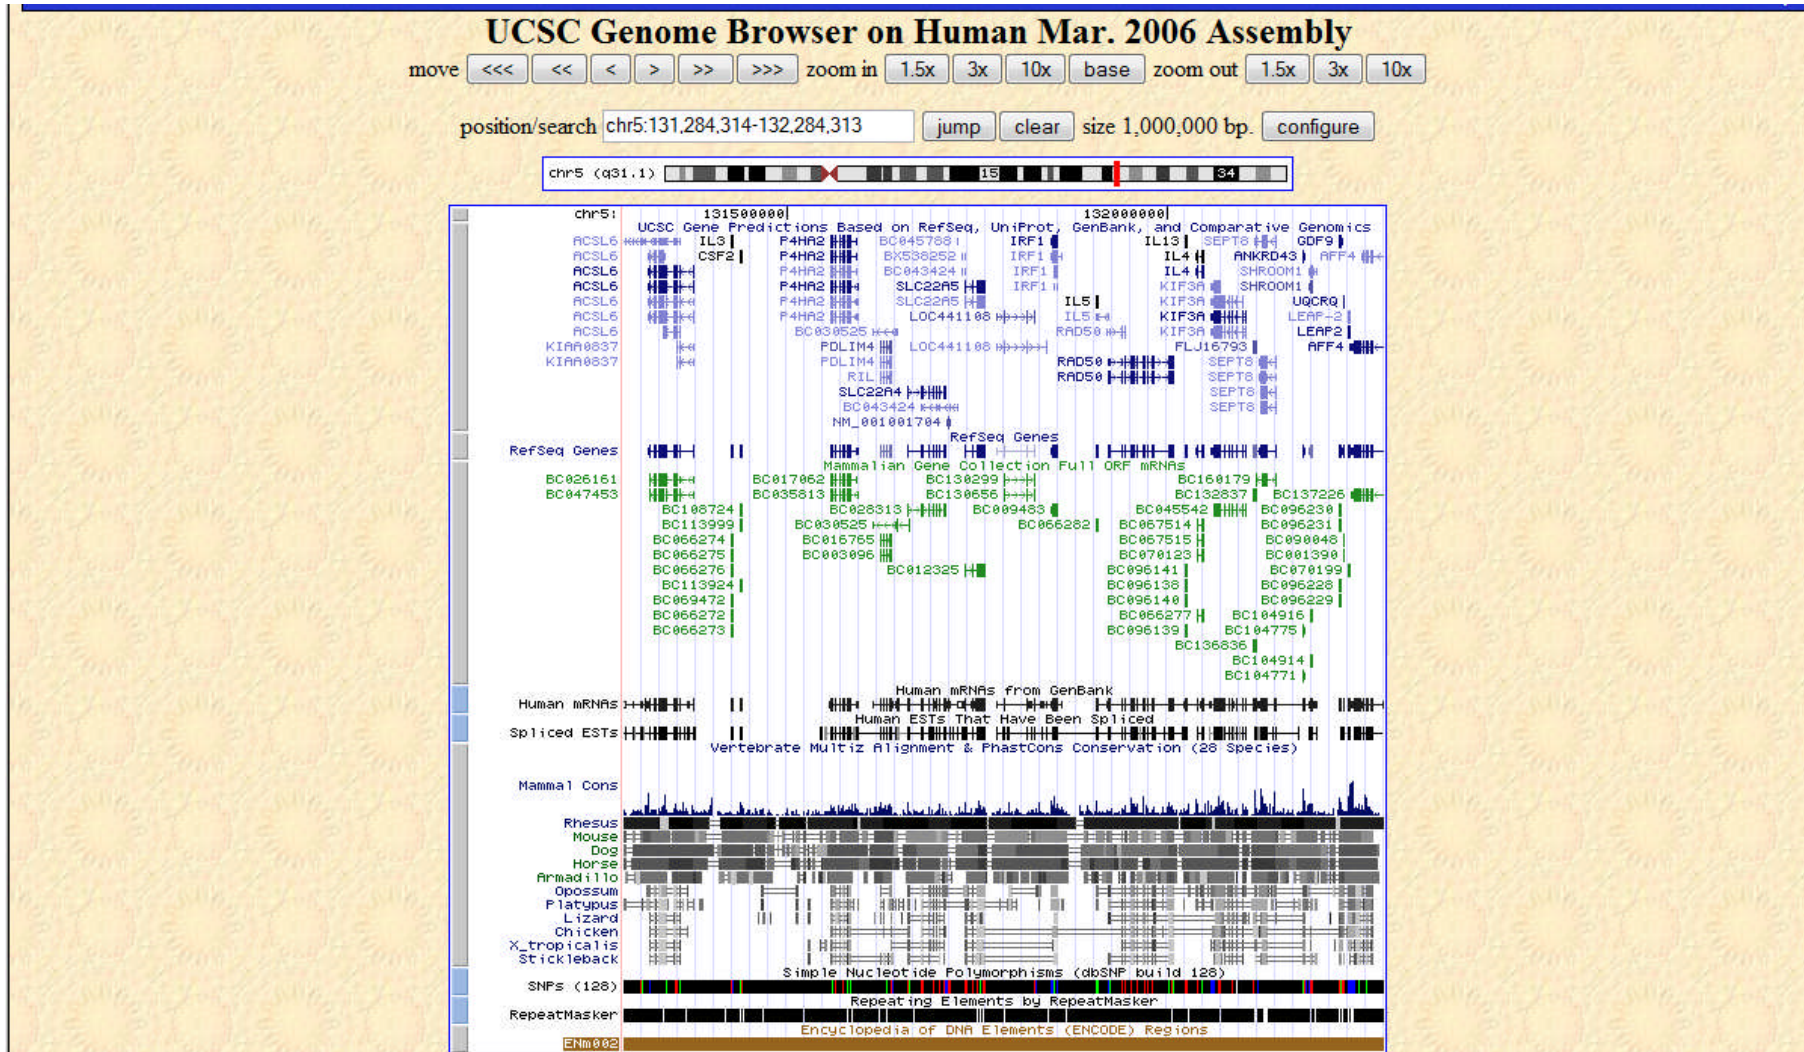

# Chromatin Structure

# DNA

# Human Genome Matching

<http://genome.ucsc.edu/ENCODE/encode.hg18.html>

# Why?

- ◆ **Wrong data model**
  - ◆ **Remote sensing guys want arrays**
  - ◆ **Which are horribly inefficient and usually very unnatural to simulate on top of tables**

# Why?

- ◆ **Wrong operations**
  - ◆ **Consider two satellite imagery data sets, one with 50m cells in lat-long and one with 75 meter cells in mercator**
  - ◆ **Need to regrid one to the other as a DBMS operation**
    - ◆ **Regrid needs to be built in**

# Why?

- ◆ **Wrong features**

- ◆ **Need provenance (i.e. ability to tell how a data element was derived)**

- ◆ **Requires a log of all operations and some provenance-oriented operations**

- ◆ **And repeatability (i.e. rederive the scientific calculation if necessary)**

- ◆ **Requires no-overwrite storage and time-travel**

# Net Result

- ◆ **Science does not use RDBMS (for anything other than metadata)**
- ◆ **Crying need not being met by current systems!**
- ◆ **A PAFS effort by TPC could change all this!!**

# Same Story

- ◆ In RDF
- ◆ In Web 2.0 companies
- ◆ In real-time data manipulation
- ◆ In Map-Reduce style computing

# So What is the Best Route Forward?

- ◆ **Best benchmarks are written by one person (e.g. debit-credit)**
  - ◆ **Typically in small numbers of days**
  - ◆ **And reviewed by the community in small numbers of weeks**
  - ◆ **And adopted in months (not years or decades)**

# So What is the Best Route Forward?

- ◆ There are **lots** of academic benchmarks that fit this model and have gained traction, e.g.
  - ◆ Linear road (streaming data)
  - ◆ MR benchmark (MR vs DBMS)
  - ◆ Madden/Abadi RDF benchmark

# So What is the Best Route Forward?

- ◆ **Troll the research world for such things**

# So What is the Best Route Forward?

- ◆ **Involve research community in your activities**
  - ◆ **But nobody will do so with your current heavyweight process**
  - ◆ **you will have to violently streamline**

# So What is the Best Route Forward?

- ◆ **Switch from a vendor-focus to a user-focus**
  - ◆ **Only way to get PA in PAFS**

# I.e. It is Time for TPC to Reinvent Itself

- ◆ **Mantra has to be PAFS**
- ◆ **Streamline process**
- ◆ **Involve research community**
- ◆ **New charter!**
- ◆ **Everybody should do this once a decade – you are a decade late**

# Otherwise

- ◆ **TPC will become a legacy world only relevant in some traditional business data processing areas**
- ◆ **i.e. you will walk into the sunset of irrelevance**
